

# Elasticity - II

Stress  $\rightarrow$  Cause of deformation

Volume stress -

Forces act in such a way that

- i) At any point the force ( $F$ ) is normal to the surface
- ii) magnitude of the force on any small surface area ( $\Delta S$ ) is directly proportional to the area

Forces acting everywhere on the surface

$$\text{Volume stress} = \frac{F}{A} \rightarrow \text{force per unit area}$$

Strain  $\rightarrow$  Effect of deformation  $\rightarrow$  Relative change

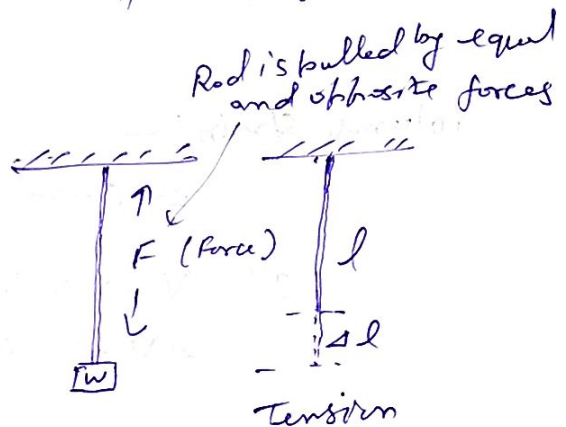

in the dimension or shape of the object due to an applied stress

Longitudinal strain:

$l \rightarrow$  length of the rod

$\Delta l \rightarrow$  change in length

$$\text{Longitudinal strain} = \frac{\Delta l}{l}$$

~~It~~

If length increases from its natural length, longitudinal strain is called  $\rightarrow$  tensile strain

If it decreases from its natural length  $\rightarrow$  compressive strain

Shearing strain (or shear):

Shape of the body changes volume remains unchanged.

→ Faces are displaced due to the tangential forces acting parallel to the faces

→ Forces are parallel to the surfaces  
 → Resultant force = 0  
 Total Torque = 0

Body with a square cross section

$$\text{Shearing strain} = \frac{DD'}{DA} = \frac{a}{b}$$

Volume strain: -

→ change in volume due to applied stress

If  $V \rightarrow$  volume of unstressed body,

$\Delta V \rightarrow$  change in volume,

$$\text{Volume strain} = \frac{\Delta V}{V}$$
