

Series the single the principle selection
of the Nicol's being θ . Find
the relative error in the intensity
due to an error $\Delta\theta$ in the setting
of the second Nicol \rightarrow

Ans! Nicol prism \rightarrow

It is an optical device used or it is an optical made from a calcite for producing and analysing plane polarised light. It was invented by William Nicol in 1828. who was an expert in cutting and polishing gems and

crystals.

Construction \rightarrow The Nicol prism is made in such a way that it eliminates one of the two rays by total internal reflection. It is generally found that the ordinary ray is eliminated and only the extra

ordinary ray is transmitted through
the prism.

A calcite crystal PQRS
about three times as long as it is
wide is taken. PQRS and faces PS
and QR are cut such that the angles
in the principle section
become 68° and 112° instead
of 71° and 109° . The crystal is then
cut apart along the plane P'Q'
and perpendicular to both the
principle

Notations

selection and the end faces
 P's and Q R'. The two cut
 surface are ground and polished
 optically flat. These are then
 cemented together by Canada balsam
 which is a transparent liquid
 of refractive index 1.55 for sodium
 light. The crystal is then enclosed
 in a tube blackened inside.

Action \rightarrow When a ray Am of unpolarised
 light nearly parallel to SR'
 is incident on the face P's it
 is up into two refracted rays are
 plane polarised. The o-ray has
 vibration perpendicular to the princi-
 ple section of the crystal and the

E-ray has vibration in principle section.
8 Now the refractive index of
• Canada balsam (1.55) is less than the
9 refractive index of calcite for the o-
• ray (1.658), but greater than the
10 refractive index of calcite for
• the E-ray (1.486). Therefore
11 When the o-ray reaches the layer
• of Canada balsam. It is passing
12 from an optically denser to a
• rarer medium. Hence, the o-ray
13 is totally reflected at calcite-balsam
• surface and is absorbed by the
14 tube containing the crystal. Since
• E-ray is plane-polarised the light
15 emerging from the Nicol is plane
• polarised with vibrations parallel to
16 the principle section. These vibra-
• tion are parallel to the shorter
17 diagonal of the end face of the
• crystal. In this we can produce
18 plane polarised light with the
• help of a Nicol prism.

uses \rightarrow The Nicol prism be used
both as a polariser and analyser

When unpolarized beam
8 of light is incident on a Nicol prism
• N_1 the light emerging out of it
9 is plane polarized and has
• vibration parallel to its principle
10 section. If now this light is made to
• pass through a second Nicol N_2 , the
11 principle section of which is
• parallel to its principle section
12 and hence are completely transmitted
• as shown in fig. The intensity
13 of the emergent beam is maximum,
•

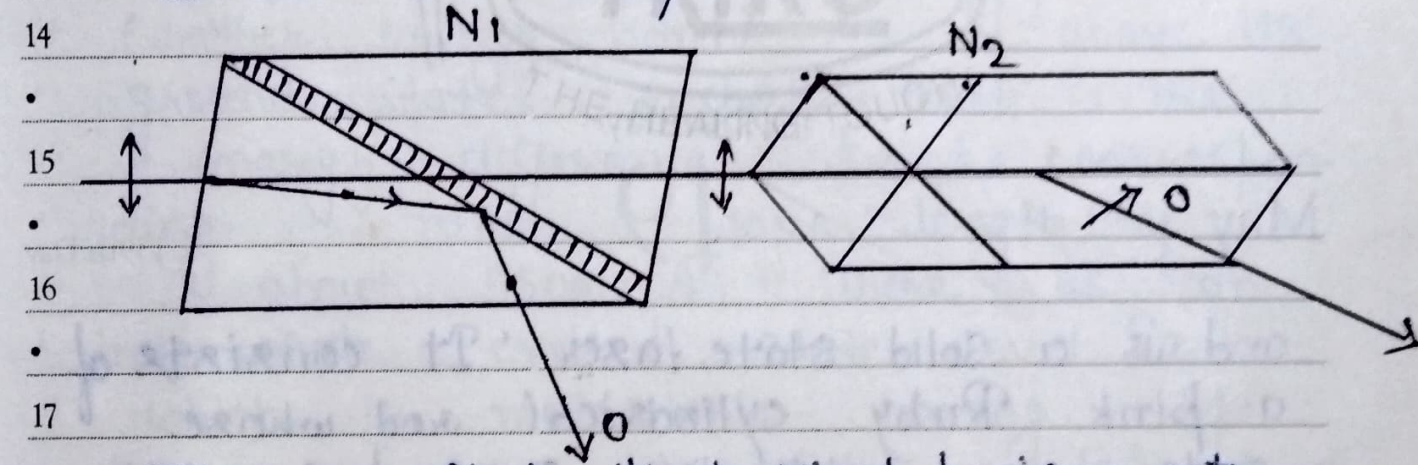

14 Now if the Nicol N_2 is
• rotated such that its principle
15 section becomes perpendicular to
• that of N_1 , then the vibration of
16 incident light as o-vibrations for N_2 .
• Hence ~~no~~ no light emerges from
17 the second Nicol N_2 . In
• this position the two Nicols
18 are said to be crossed,
•

When the
Nicol N_2 (analyser) is further rotated,
the two Nicols are again in
parallel position. In this

the E-ray is again transmitted through the Nicol. N_2 .

The first Nicol polariser the light and is called polariser. The second Nicol analyses the polarized light and is called the analyser.

Thus we find that Nicol prism acts both as a polariser and an analyser.
